

# COMP1730/COMP6730

## Programming for Scientists

### Control, part 2: Iteration

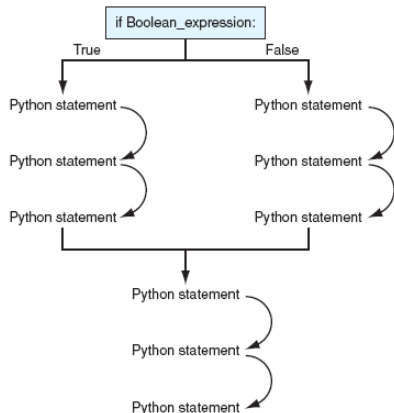

# Outline

- \* Iteration: The `while` statement with examples
- \* Common problems with loops.

# Program control flow

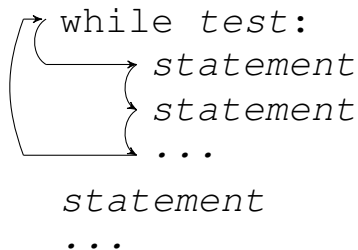

**FIGURE 2.1** Sequential program flow.

**FIGURE 2.2** Decision making flow of control.

# Iteration

while *test*:  
    *statement*  
    *statement*  
    ...  
*statement*  
...

The diagram shows a code block for a while loop. A large curved arrow on the left side starts from the bottom of the loop body and points back to the beginning of the loop, indicating that the statements are repeated. The code consists of a 'while test:' line, followed by two indented 'statement' lines and an ellipsis, then a non-indented 'statement' line and another ellipsis.

*UNTIL*

while *test*:  
    *statement*  
    *statement*  
    ...  
*statement*  
...

The diagram shows a code block for an until loop. A large curved arrow on the left side starts from the bottom of the loop body and points back to the beginning of the loop, indicating that the statements are repeated. The code consists of a 'while test:' line, followed by two indented 'statement' lines and an ellipsis, then a non-indented 'statement' line and another ellipsis.

- \* Iteration *repeats* a block of statements.
- \* A test is evaluated before each iteration, and the block executed (again) if it is true.

# Iteration statements in python

- \* The `while` loop repeats a block of statements as long as a condition is true.
- \* The `for` loop iterates through the elements of a collection or sequence (data structure) and executes a block once for each element. So `for` loops are most useful for looping a defined number of times, whereas a `while` statement is best for looping an undefined number of times.
  - See `for_loop_examples.py` for details on the use of `for` loops.

# The `while` loop statement

```
while test_expression :  
    block  
statement (s)
```

1. Evaluate test expression (converting the value to type `bool` if necessary).
2. If the value is `True`, execute the block once, then go back to 1.
3. If the value is `False`, skip the block and go on to the following statements (if any).

Image from Punch  
& Enbody

# blocks (reminder)

- \* A *block* is a (sub-)sequence of statements.
- \* A block must contain at least one statement!
- \* In python, a block is delimited by indentation.
  - All statements in the block **must be preceded by the same number of spaces/tabs** (standard is 4 spaces).
  - The indentation depth of the block following `if / else / while` : must be greater than that of the statement.
- \* A block can include nested blocks (`if`'s, etc).

# Variable assignment (reminder)

- \* A variable is a name that is associated with a value in the program.
- \* Variable assignment is a statement:  
*var\_name = expression*
  - Note: Equality is written == (two ='s).
- \* A name–value association is created by the *first* assignment to the name;
- \* *subsequent* assignments to the same name *change* the associated value.

```
→ 1 an_int = 3 + 2  
→ 2 an_int = an_int * 5
```

```
1 an_int = 3 + 2  
→ 2 an_int = an_int * 5
```

Global frame

an\_int | 5

Global frame

an\_int | 25

★ For example,

```
an_int = 3 + 2
```

```
an_int = an_int * 5
```

(From [pythontutor.com](http://pythontutor.com))

1. Evaluate expression `3 + 2` to 5.
2. Store value 5 with name `an_int`
3. Evaluate expression `an_int * 5` to 25.
4. Store value 25 with name `an_int`, replacing the previous associated value.

# Problem: Counting boxes

- \* How many boxes are in the stack from the box in front of the sensor and up?

- \* While `robot.sense_color() != ''`, move the lift up, *and count how many times*; then move the lift down that many times.

```
def count_boxes():
    num_boxes = 0
    while robot.sense_color() != '':
        num_boxes = num_boxes + 1
        robot.lift_up()
    steps_to_go = num_boxes
    while steps_to_go > 0:
        robot.lift_down()
        steps_to_go = steps_to_go - 1
    return num_boxes
```

# Problem: Solving an equation

- \* Solve  $f(x) = 0$ .
- \* The interval-halving algorithm:
  - if  $f(m) \approx 0$ , return  $m$ ;
  - if  $f(m) < 0$ , set  $l$  to  $m$ ;
  - if  $f(m) > 0$ , set  $u$  to  $m$ .

# return from a loop

- \* A loop (`while` or `for`) can appear in a function block, and a `return` statement can appear in the block of the loop.

```
def find_box(color):  
    while robot.sense_color() != '':  
        if robot.sense_color() == color:  
            return True  
        robot.lift_up()  
    return False
```

- \* Executing the `return` statement ends the function call, and therefore also exits the loop.
- \* (also read up on the `break` and `continue` statements)

# Problem: Greatest common divisor

- \* For two positive integers  $a$  and  $b$ , find the largest integer that divides  $a$  and  $b$ .
- \* Euclid's algorithm: Assuming  $a \geq b$ ,
  - $\gcd(a, b) = b$  if  $b$  divides  $a$ ;
  - $\gcd(a, b) = \gcd(b, a \% b)$ , otherwise.

# Bounded loops using `for`

- \* The iteration examples above loop an indefinite number of times (e.g. until convergence).
- \* It is often the case that we want to loop a fixed number of times.
- \* This can be done using `while` and a “loop variable”

```
j = 0 # initialise loop variable to 0
while j < 10:
    print(j)
    j = j + 1
```

# Bounded loops using `for`

- \* But a `for` statement is designed for bounded loops and is shorter as it implicitly implements the loop variable

```
for i in range(0,10):  
    print(i)
```

- \* A `for` statement is also widely used to iterate over the contents of a list or other sequence data type (covered next lecture).

```
a = ["one", "two", "three"] # list of strings  
for c in a:  
    print(c)
```

# Writing and debugging loops

# Repeat while condition is true

- \* A `while` loop repeats as long as the condition (test expression) evaluates to `True`.
- \* If the condition is initially `False`, the loop executes zero times.
- \* If no variable involved in the condition is changed during execution of the block, the value of the condition will not change, and the loop will continue forever.

# Common problems with `while` loops

- \* Loop never starts: the control variable is not initialised correctly.

```
# find smallest non-trivial
# divisor of num:
i = 1
while num % i != 0:
    i = i + 1
```

- `num % 1` is always 0!

# Common problems with `while` loops

- \* Loop never ends: the control variable is not updated in the loop block, or not updated in a way that can make the condition false.

```
i = 0
while i != stop_num:
    i = i + step_size
```

- What if `stop_num < 0`?
- or `step_size < 0`?
- or `step_size` **does not divide** `stop_num`?

# Take home message

- \* Branching (`if`) and iteration (`while` loop) are two main control mechanisms to change the sequential flow of a program.
- \* Some (but not all) recursions can be re-written as iterations to solve the same problem (and vice versa).
- \* Make sure that the test condition will evaluate to `False` at some point. Otherwise you will enter an infinite loop!
